

# 601.220 Intermediate Programming

Summer 2022, Meeting 5 (June 15th)

# Today's agenda

- Exercises 7 and 8 review
- “Day 9” material
  - Multidimensional arrays, gdb
  - Exercise 9
- “Day 10” material
  - Pointers
  - Exercise 10

# Reminders

note: for scanf, a space before %d, %f, etc. is not necessary. It's useful for %c to avoid reading a whitespace character.

- HW1 due *today*
- HW3 due Wednesday, June 22nd — be advised, much more challenging than HW1

## Exercise 7 review

Adding a function declaration (a.k.a. “function prototype”) for the `div` function:

```
float div(float a, float b);
```

A function declaration makes the compiler aware of the name, parameter type(s), and return type of a function so that calls to the function can be checked for correct usage.

## Exercise 7 review

mult function declaration:

```
float mult(float a, float b);
```

mult function definition:

```
float mult(float a, float b) {  
    return a * b;  
}
```

## Exercise 7 review

fac declaration:

```
long fac(int a);
```

fac definition (observations:  $0! = 1$ ,  $n! = (n-1)! \times n$  when  $n > 0$ ):

```
// Precondition: a >= 0
```

```
long fac(int a) {  
    assert(a >= 0);  
    if (a == 0) { return 1; } ← base case  
    return fac(a - 1) * a;  
}
```

## Exercise 7 review

find 4

bsearch function:

```
int bsearch(float ra[], int low, int high, float target) {  
    // base cases  
    if (low > high) { return -1; }  
    if (low == high) { return (ra[low] == target) ? low : -1; }  
    int mid = low + ((high-low)+1) / 2;  
    if (ra[mid] == target) { return mid; }  
    // ...recursive cases left as exercise for reader...  
}
```

"conditional operator"

## Exercise 7 review

bsearch2: The caller of bsearch2 can't know how many values were added to the results array because the size parameter is passed by value.

## Exercise 8 review

```
int concat(const char word1[], const char word2[],
           char result[], int result_capacity){
    int word1_len = strlen(word1);
    int word2_len = strlen(word2);
    if (word1_len + word2_len + 1 > result_capacity) {
        return 1; // not enough room in result array
    }
    int pos = 0;
    for (int i = 0; i < word1_len; i++) {
        result[pos] = word1[i];
        pos++;
    }
    for (int i = 0; i < word2_len; i++) {
        result[pos] = word2[i];
        pos++;
    }
    result[pos] = 0;
    return 0;
}
```

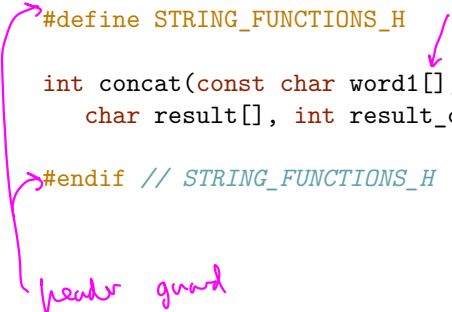

## Exercise 8 review

string\_functions.h:

```
#ifndef STRING_FUNCTIONS_H
#define STRING_FUNCTIONS_H

int concat(const char word1[], const char word2[],
           char result[], int result_capacity);

#endif // STRING_FUNCTIONS_H
```

header guard

## Exercise 8 review

string\_functions.c:

```
#include <string.h>
```

```
→ #include "string_functions.h"
```

```
int concat(const char word1[], const char word2[],  
           char result[], int result_capacity){  
    // ...code omitted...  
}
```

## Exercise 8 review

run\_concat.c:

```
#include <stdio.h>
```

```
#include <string.h>
```

```
→ #include "string_functions.h"
```

```
int main() {
```

```
    // ...code omitted...
```

```
}
```

## Exercise 8 review

make

make clean

# Makefile

CC = gcc

CFLAGS = ~~\*~~std=c99 -pedantic -Wall -Wextra

-g

→ run\_concat: run\_concat.o string\_functions.o  
\$(CC) -o run\_concat run\_concat.o string\_functions.o

run\_concat.o: run\_concat.c string\_functions.h  
\$(CC) \$(CFLAGS) -c run\_concat.c

string\_functions.o: string\_functions.c string\_functions.h  
\$(CC) \$(CFLAGS) -c string\_functions.c

→ clean:  
rm -f \*.o run\_concat

~~run\_concat.o~~

## Day 9 recap questions

- ❶ How do you declare a multi-dimensional array and pass it to a function?
- ❷ How do you initialize a multi-dimensional array using array initialization?
- ❸ What is the compile flag needed to compile a program such that we can debug it using gdb?
- ❹ How do you set a break point using gdb and check the call stack?
- ❺ Check the gdb cheat sheet and find the command to print the content of a variable per step, instead of only printing it once using `print`.

# 1. How do you declare a multi-dimensional array and pass it to a function?

Declaring a two-dimensional array:

```
char board[3][3];
```

Accessing an element:

*row 0 col 2*  

```
board[0][2] = 'X';
```

Note that by convention, the first index is “rows” and the second index is “columns”.

## 2-D array as parameter

```
void print_board(char board[3][3]) {  
    for (int i = 0; i < 3; i++) {  
        for (int j = 0; j < 3; j++) {  
            printf("%c", board[i][j]);  
        }  
        printf("\n");  
    }  
}
```

Note that the first dimension can be omitted, but the other dimensions are required.

$$\text{index} = \text{row \#} \times \boxed{3} + \text{col}$$

row size

## 2. How do you initialize a multi-dimensional array using array initialization?

"array of arrays"

Example:

```
char board[3][3] = {  
    {'O', 'X', 'X'},  
    {'X', 'O', 'O'},  
    {'X', 'X', 'O'},  
};
```

← board[0]  
← board[1]  
← board[2]

### 3. What is the compile flag needed to compile a program such that we can debug it using gdb?

The ~~-g~~ option causes the compiler to generate debug information.

Strongly recommended for all Makefiles for C programs:

```
CFLAGS = -g -std=c99 -pedantic -Wall -Wextra
```

#### 4. How do you set a break point using gdb and check the call stack?

Set breakpoint at beginning of function:

```
→ break main  
break bsearch
```

Set breakpoint at specific source line:

```
→ break functions.c:74
```

Print call stack (all of these are equivalent):

```
where  
backtrace  
bt
```

5. Check the gdb cheat sheet and find the command to print the content of a variable per step, instead of only printing it once using `print`.

`display`

## Exercise 9

back at 11:15

- Two-dimensional arrays
- Debugging using gdb
- Breakout rooms 1–10 are “social”
- Use Slack to let us know if you have questions

## Day 10 recap questions

- ❶ What is a pointer?
- ❷ If `a` is an `int` variable, and `p` is a variable whose type is *pointer-to-int*, how do you make `p` point to `a`?
- ❸ If `p` is a *pointer-to-int* variable that points to an `int` variable `a`, how can you access the value of `a` or assign a value to `a` without directly referring to `a`? Show examples of printing the value of `a` and modifying the value of `a`, but without directly referring to `a`.
- ❹ When calling `scanf`, why do you need to put a `&` symbol in front of a variable in which you want `scanf` to store an input value?
- ❺ Trace the little program below and determine what the output will be.

# 1. What is a pointer?

A pointer represents the *address*, or in other words, the *location* of a variable.

With a pointer to a variable, you can *indirectly* access the variable, either to use the value stored in the variable, or to modify the value stored in the variable.

2. If `a` is an `int` variable, and `p` is a variable whose type is *pointer-to-int*, how do you make `p` point to `a`?

```
int a;  
int *p;  
p = &a;
```

& is the “address-of” operator. It gives you a pointer that points to the variable to which it is applied.

Visual representation:

3. If `p` is a *pointer-to-int* variable that points to an `int` variable `a`, how can you access the value of `a` or assign a value to `a` without directly referring to `a`? Show examples of printing the value of `a` and modifying the value of `a`, but without directly referring to `a`.

To indirectly access the variable a pointer is pointing to, use the `*` operator, known as the *dereference* operator.

How to think about the dereference operator: if `p` points to `a`, then `*p` means exactly the same thing as `a`.

# Dereferencing a pointer

```
// deref.c:
#include <stdio.h>
int main(void) {
    int a = 42;
    int *p;
    p = &a;
    printf("*p = %d\n", *p); // get a's value indirectly
    *p = 17;                // modify a's value indirectly
    printf("after assigning to *p, a = %d\n", a);
    return 0;
}
```

```
$ gcc -std=c99 -Wall -Wextra -pedantic deref.c
```

```
$ ./a.out
```

```
*p = 42
```

```
after assigning to *p, a = 17
```

#### 4. When calling scanf, why do you need to put a & symbol in front of a variable in which you want scanf to store an input value?

By using the address-of operator (&), you are passing a pointer to the variable in which you want scanf to store the input value. scanf uses this pointer to indirectly assign to the variable.

This is a very important use of pointers: to allow a function to *indirectly* refer to a variable that it can't refer to directly. This is a way of emulating *pass by reference*.

`scanf("%d", &n)`

scanf

`int *p = ...`

5. Trace the little program below and determine what the output will be.

The program:

```
int func(float ra[], float x, float *y) {  
    ra[0] += 10;  
    x *= 20;  
    *y += 30;  
    return 40;  
}  
  
int main() {  
    float a = 1;  
    float b = 2;  
    float c[] = {3, 4, 5, 6};  
    int d;  
    d = func(c, a, &b);  
    printf("%.2f, %.2f, %.2f, %d\n", a, b, c[0], d);  
}
```

## Exercise 10

- Implement a getDate function so that its parameters are pointers to month, day, and year variables
- Breakout rooms 1–10 are “social”
- Use Slack to let us know if you have questions
